3. **Timeline:** We anticipate data analyses to be complete within ~ 1 year of when final ARIC NCS data are available.

4. **Rationale:**  
Dementia and mild cognitive impairment (MCI) are common among U.S elderly¹, yet despite their immense and growing burden relatively little is known about characteristics which lead to cognitive decline. Recent evidence, both epidemiological and pathophysiological, has suggested a possible relation between abnormal sleep
characteristics and cognitive impairment due to both cerebral vascular etiologies and Alzheimer’s disease. However, understanding of this relation is incomplete.

There are several mechanisms through which disordered sleep may lead to mild cognitive impairment and dementia: Chronic nocturnal hypoxia, sleep fragmentation, mediation through cardiovascular disease risk factors (e.g. hypertension, diabetes, inflammation), stroke (both clinical and subclinical), increases in Aβ burden, and interaction with the APOE ε4 risk allele.

Epidemiologically, to date only the Study of Osteoporotic Fractures (SOF) has prospectively evaluated the relation between objectively measured sleep characteristics and risk of incident MCI and dementia (combined outcome). After multivariate adjustment, women with sleep disordered breathing (AHI ≥15 events/hour) were 85% (95% CI: 11%-208%) more likely to develop MCI or dementia. This compelling SOF publication serves as a basis for additional hypothesis generation. Yet, it has several limitations, some of which the analyses we are proposing will be able to overcome. By using exposure data from the subset of ARIC participants who participated in the Sleep Heart Health Study (SHHS), and linking this to ARIC Neurocognitive Study (NCS) data, ARIC-SHHS will have a much larger sample size, objective assessment of sleep in middle-age, 15 years of follow-up, multifactorial comprehensive cognitive assessment, objective information on CVD risk factors, and both men and women will be represented.

5. Main Hypothesis/Study Questions:

Study question: Are abnormal sleep characteristics (inclusive of measures of hypoxia and disordered breathing, sleep fragmentation, and sleep duration) associated with greater risk of dementia and/or MCI?

Hypothesis: Abnormal sleep characteristics will be associated with greater risk of dementia and MCI. Relations will be present for all forms of cognitive impairment; however relations will be strongest for vascular cognitive impairment.

6. Design and analysis (study design, inclusion/exclusion, outcome and other variables of interest with specific reference to the time of their collection, summary of data analysis, and any anticipated methodologic limitations or challenges if present).

Study Design
Prospective cohort. We will link data from 1,892 individuals who participated in both ARIC Visit 4 and had an in-home overnight polysomnography (PSG) as part of the Sleep Heart Health Study with outcome data presently being collected as part of the ARIC NCS exam. We anticipate that about 1,000 participants will be included in this analysis.

Inclusion/Exclusion
Participants who at visit 4 scored below the sex- and race-specific 5th percentile in any of the cognitive tests will be excluded, as they may have had prevalent dementia at visit 4. All other participants with SHHS, visit 4, and NCS data will be included.
Exposures

Measures of hypoxia and disordered breathing, sleep fragmentation, and sleep duration, as previously defined in SHHS.

Hypoxia and disordered breathing

- Obstructive sleep apnea (Respiratory Disturbance Index of $\geq/\leq 15$ events/h)
- Oxygen saturation $<90\%$ ($\geq/\leq 1\%$ of sleep time)
- Sleep time in apnea or hypopnea, % (continuous)
- Total apnea or hypopnea events, n events/night

Sleep fragmentation

- Arousal index, arousals/hour (continuous)
- Wake after sleep onset, min (continuous)

Sleep duration

- Time in sleep, min (categorical; will not assume linearity)

Outcomes

Dementia and mild cognitive impairment (MCI) as classified by the ARIC-NCS events committee. The primary analysis will combine dementia and MCI. In additional exploratory analyses we will consider dementia and MCI, as well as dementia subtypes, as separate outcomes. For incidence analyses, in addition to dementia cases identified in the ARIC-NCS exam, possible dementia cases will also be gleaned from select hospitalization discharge ICD-9 codes obtained from standard ARIC follow-up surveillance and from inpatient and outpatient claims in ARIC participants enrolled in Medicare.

Confounders and effect modifiers

Age, race, sex, education, physical activity, smoking status, BMI, diabetes, inflammatory markers, hypertension, APOE $\varepsilon 4$ risk allele.

Data analysis

Our analysis will follow recommendations presently being developed by the ARIC-NCS Analysis Committee. The date of the SHHS exam will serve as baseline for the current analysis. Visit 4 participant characteristics will be described using means and proportions stratified by levels of the exposures.

For the primary analysis, logistic regression will be used to estimate prevalence ratios of the relation of sleep characteristics to prevalent dementia and MCI, defined by NCS examination/evaluation. When Medicare and hospitalization data are included in the outcome, Cox proportional hazards regression will be used.

We anticipate running a series of models, using ‘baseline’ covariates collected at ARIC visit 4. The first will likely adjust for demographics (age, race, sex), while further models will additionally adjust for behaviors, psychological characteristics (e.g. depressive symptoms), and physiologic characteristics (e.g. BMI, inflammatory markers, diabetes, hypertension). We also anticipate exploring whether age, sex, and APOE $\varepsilon 4$
modify relations between sleep and cognitive impairment by including interaction terms in the models. Selection bias is of concern in this analysis, as people who attend the ARIC-NCS exam may have better cognitive functioning than those who do not attend or died, and may also differ from the rest of the ARIC population in regard to their sleep characteristics. To help address this, inverse probability weighting will be used to model selection into the study using information in ARIC as well as TICS and hospital records.

7.a. Will the data be used for non-CVD analysis in this manuscript?  ____ Yes  ___X_ No

b. If Yes, is the author aware that the file ICTDER03 must be used to exclude persons with a value RES_OTH = “CVD Research” for non-DNA analysis, and for DNA analysis RES_DNA = “CVD Research” would be used?  ____ Yes  ____ No
(This file ICTDER has been distributed to ARIC PIs, and contains the responses to consent updates related to stored sample use for research.)

8.a. Will the DNA data be used in this manuscript?
___X (only APOE ε4)___ Yes  ____ No

8.b. If yes, is the author aware that either DNA data distributed by the Coordinating Center must be used, or the file ICTDER03 must be used to exclude those with value RES_DNA = “No use/storage DNA”?
___X___ Yes  ____ No

9. The lead author of this manuscript proposal has reviewed the list of existing ARIC Study manuscript proposals and has found no overlap between this proposal and previously approved manuscript proposals either published or still in active status. ARIC Investigators have access to the publications lists under the Study Members Area of the web site at: http://www.cscu.unc.edu/ARIC/search.php

___X___ Yes  _______ No

10. What are the most related manuscript proposals in ARIC (authors are encouraged to contact lead authors of these proposals for comments on the new proposal or collaboration)?

MS#884: Measures of Cognitive Function in Persons with Varying Degrees of Sleep-Disordered Breathing: The Sleep Heart Health Study (Shahar 2nd author).

MS#1298: Sleep-disordered breathing and risk of incident cerebrovascular disease: The Sleep Heart Health Study (Shahar coauthor, Punjabi senior author)

11.a. Is this manuscript proposal associated with any ARIC ancillary studies or use any ancillary study data?  ____X___ Yes  ____ No
11.b. If yes, is the proposal
X A. primarily the result of an ancillary study

1995.12 Sleep Heart Health Study (SHHS) (PI: Punjabi NM)
2008.06 Prediction of cognitive impairment from mid-life vascular risk factors and markers: The ARIC Neurocognitive Study (ARIC-NCS) (PI: Coresh J)
(Under review)
2013.02 Sleep disordered breathing and incident cognitive decline and dementia: The ARIC Study (PI: Lutsey PL)

B. primarily based on ARIC data with ancillary data playing a minor role (usually control variables; list number(s)* __________ __________ __________)

*ancillary studies are listed by number at http://www.cscc.unc.edu/aric/forms/

12a. Manuscript preparation is expected to be completed in one to three years. If a manuscript is not submitted for ARIC review at the end of the 3-years from the date of the approval, the manuscript proposal will expire.

12b. The NIH instituted a Public Access Policy in April, 2008 which ensures that the public has access to the published results of NIH funded research. It is your responsibility to upload manuscripts to PUBMED Central whenever the journal does not and be in compliance with this policy. Four files about the public access policy from http://publicaccess.nih.gov/ are posted in http://www.cscc.unc.edu/aric/index.php, under Publications, Policies & Forms. http://publicaccess.nih.gov/submit_process_journals.htm shows you which journals automatically upload articles to Pubmed central.
