1. Full Title: The Association of Head Injury and Cognition, Mild Cognitive Impairment, and Dementia in the ARIC Study

b. Abbreviated Title (Length 26 characters): Head Injury and Cognition/MCI/Dementia

2. Writing Group:
   Andrea Schneider  First Author - Johns Hopkins University
   Rebecca Gottesman  Senior Author - Johns Hopkins University

   Coauthors (in alphabetical order):
   Josef Coresh  Johns Hopkins University
   Silvia Koton  Tel Aviv University
   Lawrence Latour  NIH/NINDS
   Menglu Liang  Johns Hopkins University
   Thomas Mosley  University of Mississippi Medical Center
   Elizabeth Selvin  Johns Hopkins University
   Christine Turtzo  NIH/NINDS
   Others Welcome

I, the first author, confirm that all the coauthors have given their approval for this manuscript proposal. ALCS  [please confirm with your initials electronically or in writing]

First author: Andrea L.C. Schneider, MD, PhD
Address: 2024 East Monument Street, Suite 2-634
         Departments of Neurology and Epidemiology
         Johns Hopkins School of Medicine and Bloomberg School of Public Health
         Baltimore, Maryland 21287
Phone: 443-827-2352  Fax: 410-955-0476
Email: achris13@jhmi.edu

ARIC author to be contacted if there are questions about the manuscript and the first author does not respond or cannot be located (this must be an ARIC investigator).

Name: Rebecca Gottesman, MD PhD
Address: The Johns Hopkins Hospital
         Departments of Neurology and Epidemiology
         600 North Wolfe Street, Phipps 446D
         Baltimore, Maryland 21287
Phone: 410-614-2381  Fax: 410-955-0672
E-mail: rgottesm@jhmi.edu
3. **Timeline:**
Data is currently available. We anticipate that analyses will be performed within 6-12 months of manuscript proposal approval with a goal to submit an abstract to a conference within this time period. We anticipate submitting the manuscript for publication within 1-2 years of manuscript proposal approval.

4. **Rationale:**
The burden of head injury (traumatic brain injury; TBI) in the United States is high. Each year, 1.7 million individuals sustain a TBI, 1.4 million of these individuals are treated in emergency departments with 275,000 hospitalizations and 52,000 deaths\(^1,2\). The estimated cost of TBI in 2010 was estimated to be approximately $76.5 billion\(^2\).

Several prior studies have investigated short and long-term associations between TBI and cognition and dementia\(^3-6\). One study found no association of TBI with cognitive test score or with incident MCI/dementia, but this study had only 2 years of follow-up\(^7\). Other studies with longer-term follow-up (median 6-33 years) have reported associations with dementia, but these studies were limited by the use of administrative datasets and by defining both TBI and dementia by ICD-9 codes\(^4,6\). Another recent study has suggested that a history of TBI is associated with acceleration of the age of onset of cognitive impairment by 1-2 years\(^7\). Mechanisms by which TBI is associated with cognitive dysfunction and MCI/dementia include both primary and secondary brain injury. Primary injury includes axonal injury, contusion, and hematoma and secondary injury occurs via oxidative stress, inflammation, excitotoxicity leading to axonal degeneration and cell death, all of which cumulatively are hypothesized to lead to cognitive dysfunction and MCI/dementia\(^8\).

We propose to investigate prospective long-term associations of head injury with both cognitive change and adjudicated MCI/dementia in a community-based population.

5. **Main Hypothesis/Study Questions:**
We hypothesize that a history of head injury will be associated with greater cognitive decline over follow-up. We also hypothesize that a history of head injury will be associated with increased prevalence of MCI/dementia.

6. **Design and analysis (study design, inclusion/exclusion, outcome and other variables of interest with specific reference to the time of their collection, summary of data analysis, and any anticipated methodologic limitations or challenges if present).**

**Study Design:**
Prospective cohort study to examine the association between history of head injury (data collected between 1993 and 2013) and cognition (data collected in 1996-1998 and 2011-2013). For this analysis, head injury will be defined using Visit 3 and Visit 4 data. We will additionally consider time-varying head injury (ever/never) to account for head injury events occurring after visit 4.
Cross-sectional study to examine the association between history of head injury (data collected between 1993 and 2013) and MCI/dementia (assessed in 2011-2013). For this analyses, head injury will be defined using data from Visit 3, Visit 4, and Visit 5.

**Inclusion/Exclusion Criteria:**
- **Inclusion:** All ARIC participants with head injury and cognition and MCI/dementia (will have two separate analysis populations – one for cognition data and one for MCI/dementia data).
- **Exclusion:** Non-white and non-black participants, black participants from the Washington County, Maryland or Minneapolis, Minnesota field centers, participants missing data on covariates included in statistical models.

**Exposure: Head Injury:**
Self-reported data on head injury was collected at ARIC visit 3 (1993-1995), visit 4 (1996-1998), and visit 5 (2011-2013, in the NCS subset). The following variables are available:
- **Visit 3:**
  - amha5: Have you ever had a head injury which led you to see a physician or seek hospital care?
  - amha5a: How many times has this happened?
  - amha5b: How many of these head injuries resulted in your losing consciousness, no matter how briefly?
  - amha5c In what year was your last head injury for which you sought medical care?
- **Visit 4:**
  - hhxd10: Have you ever had a major head injury? That is, one that resulted in your losing consciousness, no matter how briefly, or that led you to see a physician or seek hospital care?
  - hhxd10a: How many times has this happened?
  - hhxd10b: How many head injuries resulted in your losing consciousness, no matter how briefly?
  - hhxd10c: In what year was your last head injury for which you lost consciousness sought medical care?
- **Visit 5:**
  - nhx2: Have you ever had a head injury that resulted in loss of consciousness?
  - nhx2a: Have you had a head injury with extended loss of consciousness (>5 minutes)?
  - nhx2b: Have you had a head injury that resulted in long-term problems or dysfunction?

The ARIC study also collects data on hospitalizations via annual telephone contact with study participants and through active surveillance of hospitalizations occurring in the study community hospitals. Hospitalization data is currently available through December 31, 2012. The CDC has previously used the following ICD-9 codes to define head injury:
- 800.xx = Fracture of vault of skull
- 801.xx = Fracture of base of skull
- 803.xx = Other and unqualified skull fractures
- 804.xx = Multiple fractures involving skull or face with other bones
- 850.xx = Concussion
- 851.xx = Cerebral laceration and contusion
- 852.xx = Subarachnoid subdural and extradural hemorrhage following injury
- 853.xx = Other and unspecified intracranial hemorrhage following injury
- 854.xx = Intracranial injury of other and unspecified nature
- 959.01 = Head injury, unspecified

Using the above self-reported and hospitalization data on head injury we will create the following exposure definitions:
- Ever/never head injury
- Counts of head injury events
- Length of time between head injury and cognition measurement (baseline) and MCI/dementia assessment

**Outcome: Cognition:**
Cognitive testing measured by DWRT, DSST, and WFT was performed at ARIC visit 4 (1996-1998) and visit 5 (2011-2013).

The DWRT\(^{11}\) is a test of verbal learning and recent memory. Participants were given 10 common nouns that they were asked to learn by using each word in one or two sentences. After a five-minute delay, participants were given 60 seconds to recall the 10 words. The score is the number of words correctly recalled.

The DSST\(^{12}\) is a test of executive function and processing speed. Participants were asked to translate numbers to symbols using a key. The score (range 0-93) is the total number of numbers correctly translated to symbols within 90-seconds.

The WFT\(^{13}\) is a test of executive function and language, and tests the ability to spontaneously generate words beginning with a particular letter, excluding proper names or places. Participants were given 60 seconds for each of the letters “F”, “A”, and “S”. The score is the total number of words generated across the three trials.

We will perform analyses using the raw cognitive test scores and using z-scores that were generated by the ARIC coordinating center for each cognitive test. We will also perform analyses using a global z-score. The coordinating center also averaged test z-scores to create global z-scores, which were then standardized using the visit 2 global z mean and standard deviation.

**Outcome: Mild Cognitive Impairment (MCI) and Dementia:**
Diagnoses of MCI and dementia were assigned at ARIC visit 5 (2011-2013) were based on an algorithm based on the formulation of MCI and dementia laid out in the National Institute on Aging - Alzheimer’s Association workgroups. MCI was defined as at least one domain score worse than -1.5 Z, a CDR-SB >0.5 and <3, an FAQ <5 and decline below the 10th percentile on one test or below the 20th percentile on two tests in the ARIC cognitive test battery. Dementia was defined as >1 cognitive domain worse than -1.5 Z and a CDR-SB >3 and FAQ>5 and decline below the 10th percentile on one test or below the 20th percentile on two tests in the ARIC cognitive test battery. Dementia was defined as >1 cognitive domain worse than -1.5 Z and a CDR-SB >3 and FAQ>5 and decline below the 10th percentile on one test or below the 20th percentile on two tests in the ARIC cognitive test battery.
cognitive test battery. In addition, a low MMSE score (<21 for whites or <19 for blacks), even in the absence of more complete cognitive testing, was regarded as diagnostic of dementia. A group of 8 ARIC clinicians (4 physicians [DK, BW, RG and GM] and 4 neuropsychologists [MA, OA, TM, and LC]) reviewed the full battery of testing and assessments on all of the discordant individuals, a subset of those with concordant assessments and examinations, and all dementia cases. For individuals in whom the reviewers disagreed, a third reviewer evaluated the protocol and rendered a deciding vote.

Etiological diagnoses were assigned and designated as primary or secondary diagnoses. The following etiological diagnoses were included: Alzheimer disease, cerebrovascular disease related, Lewy body disease, depression/psychiatric disorders, medication-related, alcohol-related, trauma-related, other neurodegenerative disorders (PSP, corticobasal syndrome, Huntington disease, HIV dementia, etc.), systemic disorder with major impact on brain function (e.g. severe heart failure, active cancer, severe connective tissue disease), and cognitive disorder of uncertain etiology.

**Covariates:**
The following covariates (assessed at ARIC visit 4 for cognition analyses and visit 5 for MCI/dementia analyses unless otherwise specified) will be included in statistical models: age (years; continuous), sex (male; female), race/center (Minnesota whites; Maryland whites; North Carolina whites; North Carolina blacks; Mississippi blacks), education (assessed at ARIC visit 1, <high school; high school, GED, vocational school; college, graduate, professional school), physical activity (assessed at ARIC visit 1, ordinal score); hypertension (systolic blood pressure ≥140 mmHg, diastolic blood pressure ≥90 mmHg, or medication use), diabetes (self-report physician diagnosis, medication use, fasting glucose ≥126 mg/dl, or HbA1c ≥6.5%), cardiovascular disease (adjudicated events), and APOE ε4 genotype (0, 1, or 2 ε4 alleles).

**Potential Effect Modifiers:**
We will formally test for interaction by age, sex, race, and APOE ε4 genotype. We will perform stratified analysis if we observe evidence for significant effect modification.

**Data Analyses:**
Characteristics of the included study population will be described overall and stratified by history of head injury. Characteristics will be compared between head injury groups using t-tests for continuous variables and chi-square tests for categorical variables.

We will use adjusted linear regression models to assess the association of head injury with change in cognition between Visit 4 and Visit 5. In this analysis, we will consider using a time-varying head injury (ever/never) variable to account for head injury events occurring after visit 4. We will use adjusted logistic regression models to assess the association of head injury with MCI and dementia outcomes (including subtypes). Given the attrition among the population at Visit 5, we will explore the use of multiple imputation and inverse probability of attrition weighting in our analyses.

We will perform three statistical models:
- Model 1: adjusted for demographic variables: age, sex, and race/field center.
- Model 2: adjusted for Model 1 + education, smoking status, and physical activity.
- Model 3: adjusted for Models 1 and 2 + hypertension, diabetes, cardiovascular disease, and APOE ε4 genotype.

**Limitations:**
A limitation of this study is the use of self-reported and hospitalization ICD-9 codes to define head injury. However, the CDC has previously used defined head injury using ICD-9 codes.\(^9\).\(^10\) We do not have details regarding the type of injury that occurred or details on treatment received. Additionally, as with any observational study, we will not be able to rule out the possibility of residual confounding in our analyses.

7.a. Will the data be used for non-CVD analysis in this manuscript? ____ Yes  ____X__ No

b. If Yes, is the author aware that the file ICTDER03 must be used to exclude persons with a value RES_OTH = “CVD Research” for non-DNA analysis, and for DNA analysis RES_DNA = “CVD Research” would be used? _____ Yes  ____ No

(This file ICTDER has been distributed to ARIC PIs, and contains the responses to consent updates related to stored sample use for research.)

8.a. Will the DNA data be used in this manuscript? __X__ Yes  ____ No

8.b. If yes, is the author aware that either DNA data distributed by the Coordinating Center must be used, or the file ICTDER03 must be used to exclude those with value RES_DNA = “No use/storage DNA”? __X__ Yes  ____ No

9. The lead author of this manuscript proposal has reviewed the list of existing ARIC Study manuscript proposals and has found no overlap between this proposal and previously approved manuscript proposals either published or still in active status. ARIC Investigators have access to the publications lists under the Study Members Area of the web site at: http://www.cscucc.unc.edu/ARIC/search.php __X__ Yes  ____ No

10. What are the most related manuscript proposals in ARIC (authors are encouraged to contact lead authors of these proposals for comments on the new proposal or collaboration)?

11.a. Is this manuscript proposal associated with any ARIC ancillary studies or use any ancillary study data? ___Yes ___X__ No

11.b. If yes, is the proposal

___ A. primarily the result of an ancillary study (list number* ______)  
___ B. primarily based on ARIC data with ancillary data playing a minor role (usually control variables; list number(s)* __________ __________ __________)

*ancillary studies are listed by number at http://www.csc.unc.edu/aric/forms/

12a. Manuscript preparation is expected to be completed in one to three years. If a manuscript is not submitted for ARIC review at the end of the 3-years from the date of the approval, the manuscript proposal will expire.

12b. The NIH instituted a Public Access Policy in April, 2008 which ensures that the public has access to the published results of NIH funded research. It is your responsibility to upload manuscripts to PubMed Central whenever the journal does not and be in compliance with this policy. Four files about the public access policy from http://publicaccess.nih.gov/ are posted in http://www.csc.unc.edu/aric/index.php, under Publications, Policies & Forms. http://publicaccess.nih.gov/submit_process_journals.htm shows you which journals automatically upload articles to PubMed central.
